CLIMATE CHANGE AND BIODIVERSITY

Humans have increased the species extinction rate by as much as 1,000 times over background rates typical over the planet's history (*medium certainty*)

10–30% of mammal, bird, and amphibian species are currently threatened with extinction (*medium to high certainty*)

Extinctions per thousand species per millennium

Source: Millennium Ecosystem Assessment

Threatened Animal Species

Different Kinds of Extinction in the Sea

- **Commercial extinction:**
When a species becomes so rare that it no longer pays to hunt it.
- **Ecological extinction:**
When a species becomes so rare that it no longer plays its normal ecological role.

REVIEW

Climate Change and Infectious Diseases: From Evidence to a Predictive Framework

Sonia Altizer,^{1*} Richard S. Ostfeld,² Pieter T. J. Johnson,³ Susan Kutz,⁴ C. Drew Harvell⁵

Scientists have long predicted large-scale responses of infectious diseases to climate change, giving rise to a polarizing debate, especially concerning human pathogens for which socioeconomic drivers and control measures can limit the detection of climate-mediated changes. Climate change has already increased the occurrence of diseases in some natural and agricultural systems, but in many cases, outcomes depend on the form of climate change and details of the host-pathogen system. In this review, we highlight research progress and gaps that have emerged during the past decade and develop a predictive framework that integrates knowledge from ecophysiology and community ecology with modeling approaches. Future work must continue to anticipate and monitor pathogen biodiversity and disease trends in natural ecosystems and identify opportunities to mitigate the impacts of climate-driven disease emergence.

Short term: acclimation and adaptation
Long term:???

Biogeochemical cycles C and N

Since 1960:

- Flows of biologically available nitrogen in terrestrial ecosystems doubled
- Flows of phosphorus tripled

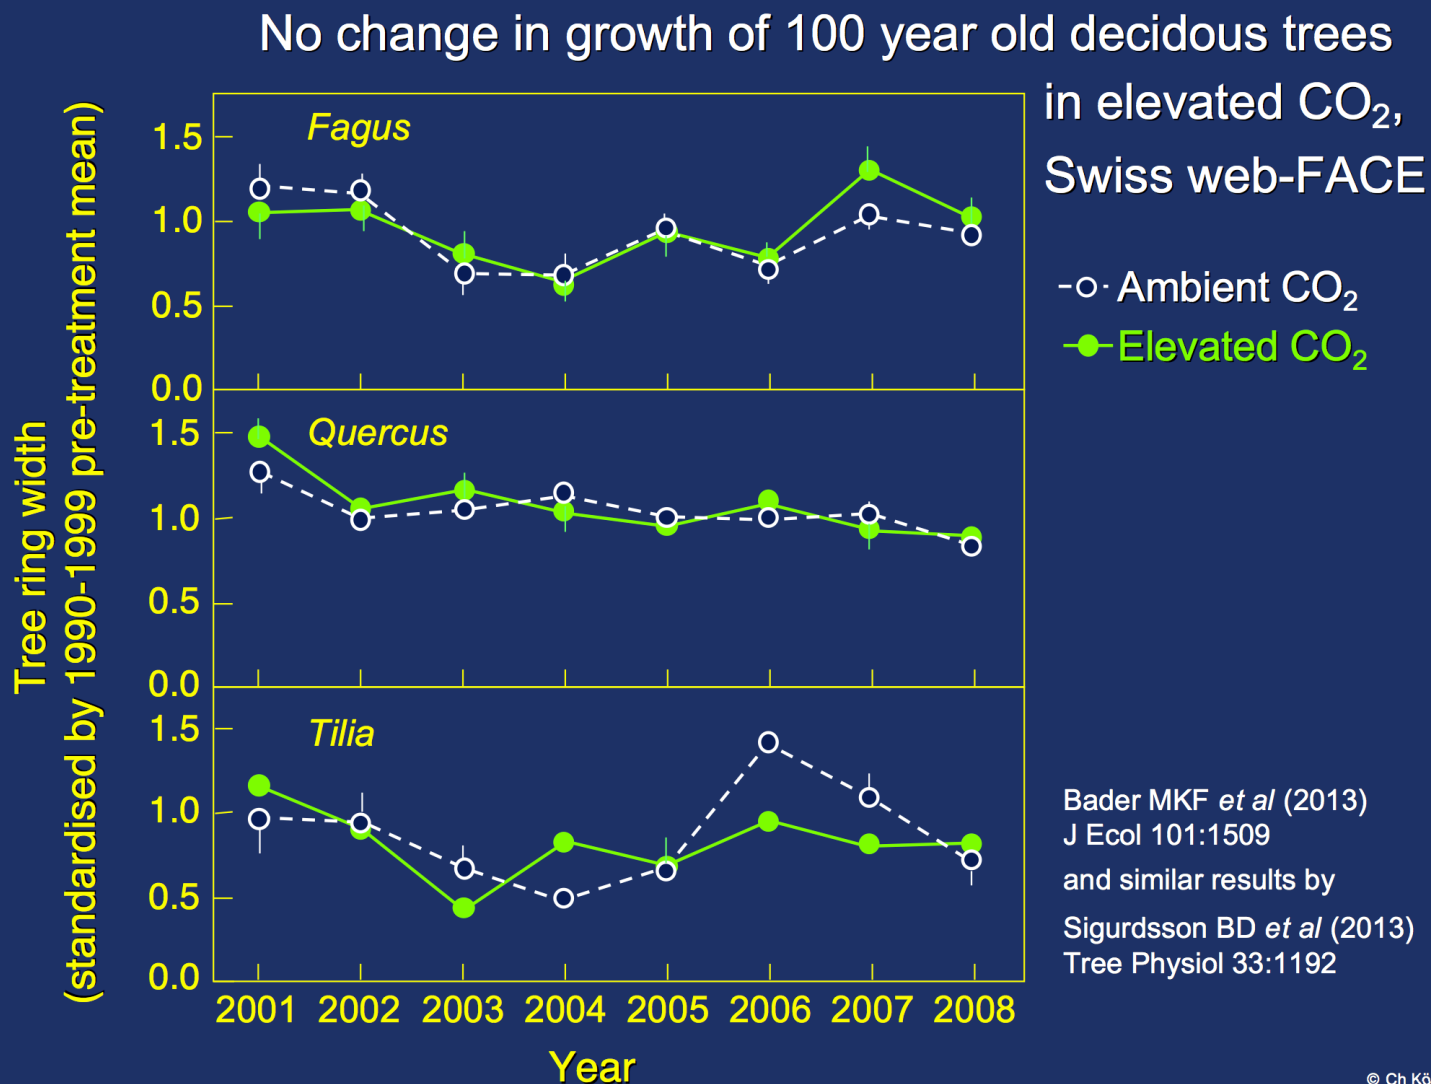

> 50% of all the synthetic nitrogen fertilizer ever used has been used since 1985

• 60% of the increase in the atmospheric concentration of CO_2 since 1750 has taken place since 1959

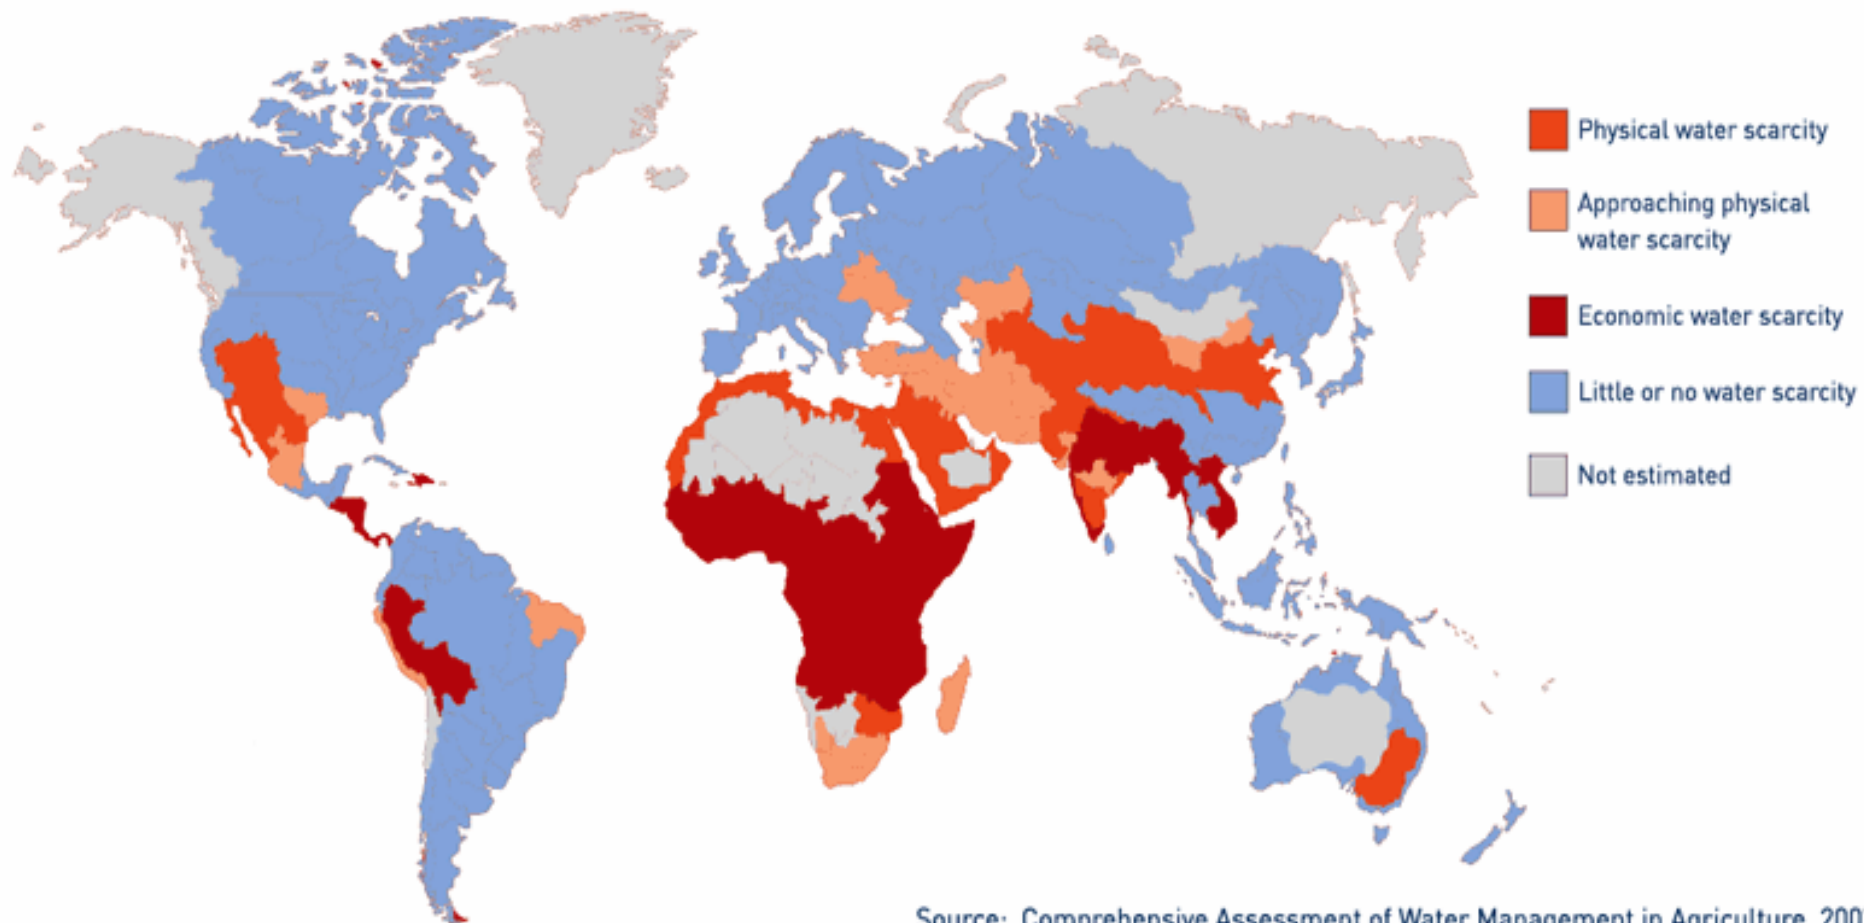

Forest productivity is not C limited...
there is no green solution to the CO₂-problem.

Christian Körner

➤ The five routes for the long term

0) Do nothing (and adapt) ← **This looks risky**

1) Reduce demand / increase efficiency

2) Renewable sources

- hydro
- biomass
- wind
- geothermal
- solar

3) Nuclear

- thermal fission
- self-breeding fission
- fusion

4) CO₂ Capture and Storage (CCS)

- at the stack
- from air

**This is
appealing, but
it's not enough**

**One
or more
of these ?**

Global emission pathways and carbon budgets

Trajectory of Global CO₂ Emission by Region

High income countries
(\$12,616 and more)

Consumption-based CO₂ emissions do not decrease even in HIC.

Upper middle income countries
(\$4,086 to \$12,615)
(China, Brazil, Iran, Malaysia, South Africa etc.)

Rapid increase in CO₂ emissions

Lower middle income countries
(\$1,036 to \$4,085)
(India, Indonesia, Philippine, Egypt etc.)

Tackling poverty; low priority of CO₂ emission mitigation

Low income countries
(\$1,035 and less)

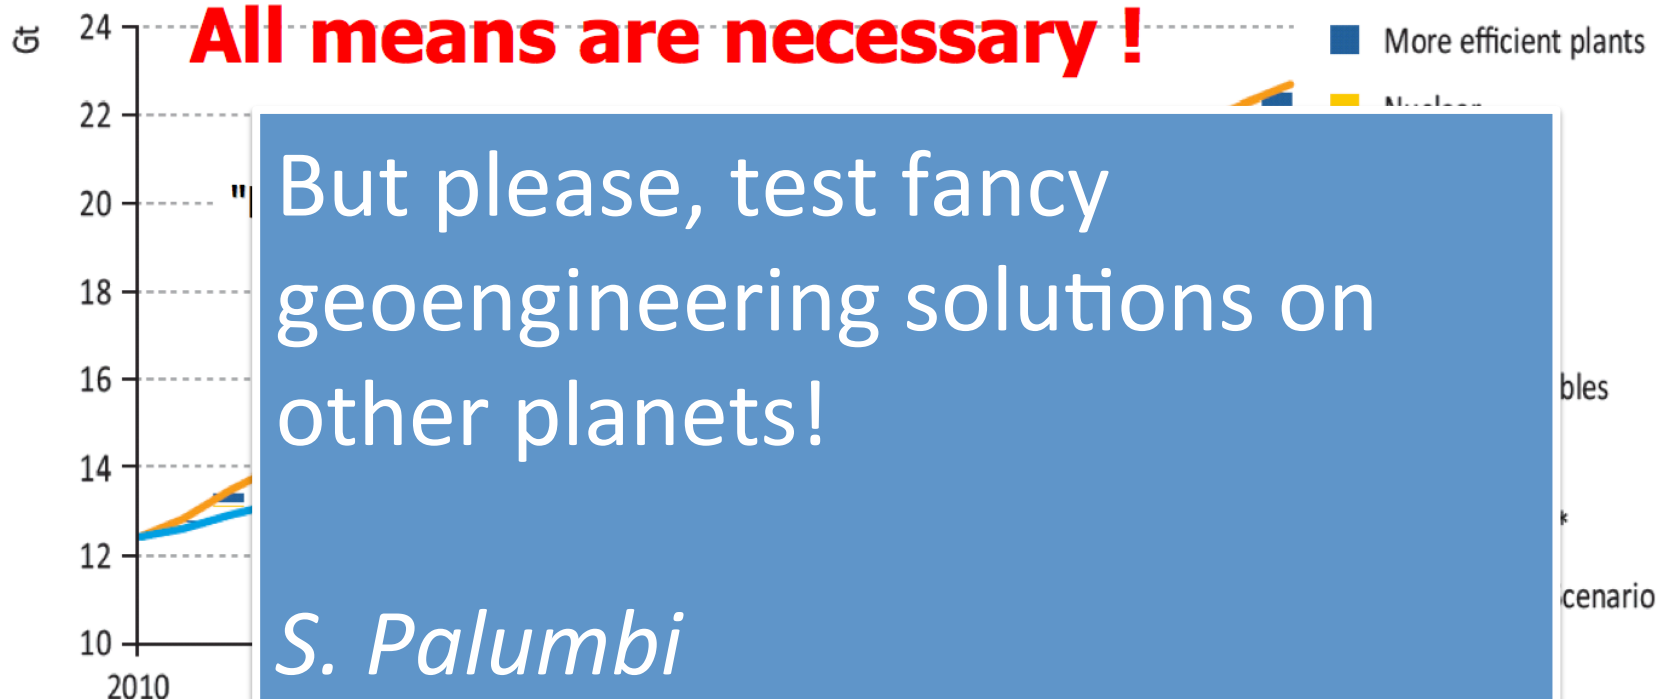

Final message

New Policies scenario

All means are necessary !

But please, test fancy
geoengineering solutions on
other planets!
